I'm going to get technical for a moment... ..the Bureau of Labor Statistics collects data on a wide array of industries. The data collected are disaggregated by several ways. These include classifying industries by occupation code, industrial classification, Census Major Group, and occupational families. Each of these has advantages and disadvantages. In this post, I'm going to focus on occupation code and industrial classifications. The reason I am doing this is because when analyzing occupation growth, a person may analyze by occupation code or by the industry in which an occupation is most common. A common problem with this is that when a job is moved from an occupation code to a new industry classification it is not always a movement to a new sector of the economy (or even a new sector of the economy in the same industry classification). One thing is for certain. Today's economic environment has made the number one occupation a commodity. One thing we have learned from the past is that any new job is an opportunity for someone else. It is up to us to make sure that this new opportunity is one that will last. That's what The Capstone is all about. But for a person looking for the next job, how do they know what jobs are growing and what jobs are in decline? My answer is the Bureau of Labor Statistics. The BLS publishes data on occupation codes and industries in two ways. First, the BLS collects data about the number of jobs in industries by using the census of establishments, which they estimate each year. So, for example, if you look at a particular occupation in the manufacturing sector (like any process engineer) and look at its industry (like electronics manufacturing
